11 Transport across epithelia. Epithelial tissues form a protective barrier around the body, both outside and inside. On the outside they mostly lock internal milieu from the environmental influence, making our skin and mucosal membranes totally impermeable and waterproof. However, on the inside, epithelial cells develop to be semipermeable dividers specialized for regulated environmental exchange.

Transport across epithelia - Cell Physiology

A General Mechanism for Airway Epithelial Ion Transport: The Transcellular Route Epithelial transport requires that epithelial cells are polarized, that is, the proteins present in the apical (airway facing) and the basolateral (blood facing) membrane are not the same. This polarization can promote net flux of sodium from lumen to interstitium.

Epithelial Tissue Function . Epithelial tissue covers the outside of the body and lines organs, vessels (blood and lymph), and cavities.Epithelial cells form the thin layer of cells known as the endothelium, which is contiguous with the inner tissue lining of organs such as the brain, lungs, skin, and heart.The free surface of epithelial tissue is usually exposed to fluid or the air, while the ...

The central subject of Epithelial Transport Physiology is to provide a comprehensive, contemporary review of epithelial transport and the responsible transporter proteins, while elucidating the wide spectrum of new methods examining epithelial transporters such as patch clamping, reconstitution, molecular biology and molecular physiology that are now available for the application to epithelial plasma membrane systems.

The objective is to promote research at the molecular and cellular level to better understand aberrations in renal epithelial transport mechanisms that may lead to disease states. The NIDDK, through its Division of Kidney, Urologic and Hematologic Diseases is the principal agency that supports fundamental and applied research directed at normal renal structure, function and regulation.
